# NUMERICAL APPROXIMATION OF DIRICHLET PROBLEM IN BOUNDED DOMAINS AND APPLICATIONS 

Oana RACHIERU, Alina STOICA<br>Faculty of Mathematics and Computer Science, "Transilvania" University, Brasov, Romania

#### Abstract

We consider numerical approximation of Dirichlet problem for the Laplace equation in a domain $D \in R^{d}$, that is we will consider the problem of finding a $C^{2}$ function $u=u(z) \in C^{2}(D) \cap C^{0}(\bar{D})$ such that $\left\{\begin{array}{l}\Delta u=0, i n D \\ u=f, \text { on } \partial D\end{array}\right.$. Using probabilistic methods we can give explicit reprezentation of solution of Dirichlet problem $u(z)=E^{z} f\left(B_{\tau_{D}}\right)$, where $B_{t}$ is a Brownian motion starting at $B_{0}=z, E^{z}$ denotes the expectation of function in $B_{\tau_{D}}$, and $\tau_{D}=\inf \left\{t \geq 0, B_{t} \notin D\right\}$ is the exit time of Brownian motion from $D$. We give a Mathematical implementation of function $u(z)$ for different choices of $f$ and domain $D$ (half-plane, unit disc, rectangle, triangle) and we apply it to obtain some numerical results.

Keywords: Brownian motion, Dirichlet problem, Laplace equation, stochastic differential equations, simulation.

## 1. INTRODUCTION

The Dirichlet Problem is named after German mathematician Gustav Lejeune Dirichlet (1805-1859) (see [3]).

The Dirichlet problem for harmonic functions always has a solution, and that solution is unique, when the boundary is sufficiently smooth and $f$ is continuous.

The goal of the present paper is to present some applications of Brownian motion in solving classical differential equations: the Dirichlet problem.

Brownian motion, named after the Scottish botanist Robert Brown in 1828, is the unique process with the following proprieties:
a) No memory, which means that $B_{t_{1}}-B_{t_{0}}, B_{t_{2}}-B_{t_{1}}, B_{t_{3}}-B_{t_{2}}, \ldots \quad$ are independent;
b) Invariance, which means that the distribution of $B_{s+t}-B_{s}$ depends only on $t$
c) Continuity which means that $t \rightarrow B_{t}$ is continuous a.s. and $t \rightarrow B_{t}$ is nowhere differentiable a.s.
d) $B_{0}=0$, with mean $E\left(B_{t}\right)=0$ and $\operatorname{variance} \operatorname{Var}\left(B_{t}\right)=t^{2}$.
Definition. A d-dimenional Brownian motion starting at $x \in R^{d}$ is a stochastic process $B_{t}$ with the following proprieties:
a) $B_{0}=0$;
b) For all $0 \leq s<t, B_{t}-B_{s}$ is a normal random variable $N(0, t-s)$;
c) $B_{t}$ is almost surly continuous.

## 2. THE DIRICHLET PROBLEM

2.1 The Dirichlet Problem. We will consider the well-known Dirichlet Problem for a domain $D \subset R^{d}$, this is we will consider the problem of finding a harmonic function in a given domain $D$, continuous on $\bar{D}$, with fixed boundary values on $\partial D$, satisfying the following initial value problem: find $u \in C^{2}(D) \cap C^{0}(\bar{D})$ which solves

$$
\left\{\begin{array}{l}
\Delta u=0 \text { in } \mathrm{D}  \tag{1}\\
\left.\mathrm{u}\right|_{\partial \mathrm{D}}(x, y)=f(x, y), \forall \mathrm{z}=\mathrm{x}+\mathrm{iy} \in \partial \mathrm{D}
\end{array}\right.
$$

where $\Delta$ denote the Laplacian operator, namely the differential operator in the variable $x=\left(x_{1}, x_{2}, \ldots, x_{n} \in R^{d}\right)$

$$
\Delta_{x}=\sum_{j=1}^{d}\left(\frac{\partial}{\partial x_{j}}\right)^{2}
$$

and $f$ is a given function, continuous on boundary of the domain $D$.

In general, the solution of the above boundary value problem may not exist. However the existence of the solution is closely related to the regularity of the boundary of the domain $D$.
Definition. A point $x \in R^{d}$ is called regular for the set $A \subset R^{d}$ if a Brownian motion starting at $x$ enters the set $A$ immediately, that is

$$
P^{x}\left(T_{A}=0\right)=1,
$$

where $T_{A}=\inf \left\{t>0: B_{t} \in A\right\}$ is the hitting time of the set $A$ by a $d$-dimensional Brownian motion $B_{t}$ starting at $x$.
Example. a) The point $z_{0}=0$ is regular for the ball $B(1,1)$, but is not regular for $B(0,1) \backslash\{0\}$.
b) In the case of unit $\operatorname{disk} U=\left\{x \in R^{2}:|x|<1\right\}$, all points on the unit circle $\partial U=\left\{x \in R^{2}:|x|=1\right\}$ are regular for $U^{c}$.

Under minimal regularity conditions on $D$ and $f$, the main result is the following:
Theorem. Let $D \subset R^{d}$ be a bounded domain for which every point of $\partial D$ is regular for $D^{C}$. If $f: \partial D \rightarrow R$ is a continuous function, then there exists a unique solution of the Dirichlet problem (1), explicitly given by

$$
\begin{equation*}
u(x)=E^{x} f\left(B_{\tau_{D}}\right) \tag{2}
\end{equation*}
$$

where

- $B_{t}$ is a d-dimensional Brownian motion starting at $x \in \bar{D}$;
$-\tau_{D}=\inf \left\{t>0: B_{t} \notin D\right\}$ is the lifetime of the Brownian motion $B_{t}$, killed on exiting $D$;
- $E^{x}$ denotes the expectation of function $f$ in the exit point $B_{\tau_{D}}$ of the Brownian motion $B_{t}$ from domain $D$.
Proof. See [4, p. 111-113].
Example. Consider the domain $D=B(0, r)$ and the function $f(x, y)=x^{2}-y^{2}$. Then the probabilistic solution is the following:

$$
u(x)=E^{x} f\left(B_{\tau_{B(0, r)}}\right)
$$

and $u(0)=E^{0} f\left(B_{\tau_{D}}\right)=\frac{1}{2 \pi \mathrm{r}} \underset{\partial \mathrm{B}(0, \mathrm{r})}{\int} f(y) d y$.
For $\partial B(0, r)$ we have $z=r e^{i t}$ and $d y=r d t$.

$$
\begin{aligned}
& \Rightarrow u(0)=\frac{1}{2 \pi r} \int_{0}^{2 \pi} f(r \cos t, r \sin t) r d t \\
& =\frac{1}{2 \pi} \int_{0}^{2 \pi}(r \cos t)^{2}-(r \sin t)^{2} d t \\
& =\frac{1}{2 \pi} \int_{0}^{2 \pi} r^{2}\left(\cos ^{2} t-\sin ^{2} t\right) d t \\
& =\frac{r^{2}}{2 \pi} \int_{0}^{2 \pi}(\cos 2 t) d t
\end{aligned}

$$
=\left.\frac{r^{2}}{2 \pi \mathrm{r}}\left(\frac{\sin 2 t}{2}\right)\right|_{0} ^{2 \pi}=0 .
$$

2.2 A numerical algorithm. We will consider $D$ to be the closed triangular domain with vertices $(-a, 0),(b, 0)$ and $(0, c)$. We will try to elaborate an algorithm for discretizing the killed Brownian motion in a simply bounded domain, using some recent results (see [1]) and [2]).

First, if $\left(X_{2^{-2 k_{n}}}^{k}\right)_{n \in N}$ is a simple random walk on the lattice $D \cap 2^{-k} Z^{2}=D_{k}$ which jumps to one of its nearest neighbors every $2^{-2 k}$ units of time, we obtain that $X_{t}^{k} \overrightarrow{k \rightarrow \infty} B_{t}, \mathrm{t} \geq 0$, for a chosen level of discretisation $k \in N$.

We consider $n=\left[t 2^{2 k}\right]$ and $X_{0}=0$.
The numerical approximation of the value $f\left(B_{t}\right)$, where $B_{t}$ is a killed Brownian motion in $D$ starting at the point $x=\left(x_{1}, x 2\right) \in D$, is given by

$$
f\left(B_{t}\right) \approx f\left(X_{t}\right) .
$$

Then the numerical approximation of expected value $E^{x} f\left(B_{t}\right)$ is given by

$$
E^{x} f\left(B_{t}\right)=\frac{f\left(X_{t}^{1}\right)+\ldots+f\left(X_{t}^{N}\right)}{N} .
$$

2.3 Using Mathematica softwere. Using Mathematica (see [5]) source presented below, we obtain the approximating domain $D_{1}$ in the Fig. 1 below, in the case of a triangle with vertices at $(-4,0),(2,0)$ and $(0,6)$ (See article).

For an arbitrarily fixed $k \in N^{*}$, note that $\left(\frac{i}{2^{k}}, \frac{j}{2^{k}}\right) \in D_{k}$ if and only if $i, j \geq 0$ and

$$
\left\{\begin{array}{l}
-\frac{i}{a 2^{k}}+\frac{j}{c 2^{k}}-1 \leq 0 \\
\frac{i}{b 2^{k}}+\frac{j}{c 2^{k}}-1 \leq 0
\end{array}\right.
$$

Which shows that $D_{k}$ can be written as follows
$D_{k}=\bigcup_{j=0}^{\left[c 2^{k}\right]}\left\{\begin{array}{l}\left(\frac{i}{2^{k}}, \frac{j}{2^{k}}\right): \\ -\left[\frac{a}{c}\left(c 2^{k}-j\right)\right] \leq i \leq\left[\frac{b}{c}\left(c 2^{k}-j\right)\right]\end{array}\right\}$

Fig. 1. The approximating domain $D_{1}$
Increasing the discretization level to $\mathrm{k}=4$, we obtain more points-neighbors, as in Fig. 2 below.

Fig. 2. The approximating domain $D_{4}$

For a given function $f$ we will obtain a numerical approximation of the expected value $E^{x} f\left(B_{t}\right)$ with respect to a Brownian motion in a triangle starting at $x$ of the value of the function $f$ at the point $B_{t}$, value that correspondes to the solution of the Dirichlet Problem $u(x)=E^{x} f\left(B_{\tau_{D}}\right)$, in the given triangular region.
