#### Abstract

This paper deals with automatic stabilization of rockets, submarines or satellites dynamics. This stabilization is based on relay-type automatic regulators, by using the minimal time criterion for optimal control with the Pontreagiune extremal principle. In this study, the state variables are the rotation angles and the control function has 2 components, which are appearing because of lateral rolling perturbations. Finaly, numeric-analytical studies are approached, and the results are graphically presented.

Key words: optimal control, control function, extreme principle of Pontreaguine, absolute stability.

## 1. INTRODUCTION

The goal of an optimal control problem (O.C.P.) of a dynamic system is to determine a set of state variables, of certain control and driving functions satisfying an optimization criterion, performing the extremization of a quality index in this way. This performance index is a functional depending on these elements and time and spatial restrictions.. Practical applications requirements for these functionals are optimal controls of the following type: achievement of minimal time, minimum fuel consumption, energy, to achieve extreme performance $[4,10,13]$. Dynamical systems from different domains are generally represented generally by nonlinear equations with parameters, while internal or external disturbances occur leading to unstable solutions related to a free balance state. The stabilization of these regimes is done by using automatic controls that actually fast reacts for optimal control and routing [3, 5-7, 12, 14]. Lurie [8], [4], [13] and Popov [11], [4], [3] methods are known to automatically adjust the absolute stabilization, with applications. This paper, for optimal control of stabilizing angular velocities of aircraft and missiles, deals with the "Minimum Time Criteria" and the Pontreaguine extremal [9], [1], [7], with results and studies in different applications [5], [6], [7]. The optimal control function will have 2 components: $\mathrm{u}\left(\mathrm{u}_{1}, \mathrm{u}_{2}\right)$.

## 2. OPTIMAL CONTROL IN ANGULAR SPEED STABILIZATION REGARDING FLUVIAL OR SPATIAL NAVES

We will consider a multi-propelled nave with axial-cylinder symmetry, as in figure 1. We choose a system of axes $\left(\mathrm{Ox}_{1} \mathrm{x}_{2} \mathrm{x}_{3}\right)$ as principal axes of inertia, where O is the masses, as a solid body rigidly fixed in point O . The nave rotate with the angular velocity
$\bar{\omega}\left(\omega_{1}, \omega_{2}, \omega_{3}\right)$, where $\omega_{\mathrm{i}}$ are the rotation speeds around the axes $\mathrm{Ox}_{\mathrm{i}}, \mathrm{i}=\overline{1,3} ; \mathrm{Ox}_{3}$ is the axis of longitudinal symmetry.

Symmetrical with these axes the ship has

FIG. 1: A multi-propelled nave turbojet propulsion generators $G_{1}\left(G_{1}^{1}, G_{1}^{2}\right)$ on $\mathrm{Ox}_{1}$ with two nozzles, $\mathrm{G}_{2}\left(\mathrm{G}_{2}^{1}, \mathrm{G}_{2}^{2}\right)$ on $\mathrm{Ox}_{2}$ and generator $\mathrm{G}_{3}$ on $\mathrm{Ox}_{3}$, with traction purpose. These reactive nozzles can create moments, being accompanied by gas dynamics wings, integrating gyroscopes, small jet shutters that can help to guide and stabilize the angular velocities regime. The controller [3], [5-7] is equipped with sensors and microprocessors for data processing and it may (with a rapid response) control the disrupted regime for optimal stabilization [12], [14]. Disturbances considered here may be due to turbines fuel, meteo external agents or environmental density. These naves may be rockets, spacecraft, capsule, modules, mega-drones or submarines, torpedoes, etc [8], [12], [14].
The angular velocities are $\omega_{1}=\mathrm{x}_{1}(\mathrm{t}), \omega_{2}=\mathrm{x}_{2}(\mathrm{t}), \omega_{3}=\mathrm{x}_{3}(\mathrm{t})$, the inertia momentums of the body are $\mathrm{I}_{1}, \mathrm{I}_{2}, \mathrm{I}_{3}$ - symmetrically $\left(\mathrm{I}_{1}=\mathrm{I}_{2}=\mathrm{I}\right)$, see figure 1 .
We write the equations of angular velocities disturbed by external moments $\mathrm{M}_{\mathrm{i}}(\mathrm{t})$ [10], [12], [14]:

$$
\left\{\begin{array}{l}
\mathrm{I}_{1} \dot{\mathrm{x}}_{1}=\left(\mathrm{I}_{2}-\mathrm{I}_{3}\right) \mathrm{x}_{2} \mathrm{x}_{3}+\mathrm{M}_{1}(\mathrm{t})  \tag{1}\\
\mathrm{I}_{2} \dot{\mathrm{x}}_{2}=\left(\mathrm{I}_{3}-\mathrm{I}_{1}\right) \mathrm{x}_{1} \mathrm{x}_{3}+\mathrm{M}_{2}(\mathrm{t}) \\
\mathrm{I}_{3} \dot{\mathrm{x}}_{3}=\left(\mathrm{I}_{1}-\mathrm{I}_{2}\right) \mathrm{x}_{1} \mathrm{x}_{2}+\mathrm{M}_{3}(\mathrm{t})
\end{array}\right.
$$

We suppose that moments $M_{i}(t)$ are caused by propelling forces $G\left(g_{1}, g_{2}, g_{3}\right)$ :

$$
\begin{equation*}
\mathrm{h}_{1}=\mathrm{l} \cdot \mathrm{~g}_{1}(\mathrm{t}), \mathrm{h}_{2}=\mathrm{l} \cdot \mathrm{~g}_{2}(\mathrm{t}), \mathrm{h}_{3}=\mathrm{h} \cdot \mathrm{~g}_{3}(\mathrm{t}) \tag{2}
\end{equation*}
$$

Taking into consideration the symmetry: $\mathrm{I}_{1}=\mathrm{I}_{2}:=\mathrm{I}$, we have:

$$
\left\{\begin{array}{l}
\dot{x}_{1}=\frac{\mathrm{I}-\mathrm{I}_{3}}{\mathrm{I}} \mathrm{x}_{2} x_{3}+\frac{1}{\mathrm{I}} \mathrm{~g}_{1}(\mathrm{t})  \tag{3}\\
\dot{\mathrm{x}}_{2}=-\frac{\mathrm{I}-\mathrm{I}_{2}}{\mathrm{I}} \mathrm{x}_{3} x_{1}+\frac{\mathrm{l}}{\mathrm{I}} \mathrm{~g}_{1}(\mathrm{t}) \\
\dot{\mathrm{x}}_{3}=\frac{\mathrm{h}}{\mathrm{I}_{3}} \mathrm{~g}_{3}(\mathrm{t})
\end{array}\right.
$$

System (1) with $\mathrm{M}_{\mathrm{i}}(\mathrm{t})=0$ is in stable equilibrium around $\mathrm{O}(0,0,0)$ (undisturbed).
Let's suppose that at $t_{0}=0$ we have the disturbed position

$$
\begin{equation*}
x_{1}(0)=\alpha_{1}, x_{2}(0)=\alpha_{2}, x_{3}(0)=\alpha_{3} \tag{4}
\end{equation*}
$$

If the traction $g_{3}(t)$ is known, than we have

$$
\begin{equation*}
\mathrm{x}_{3}(\mathrm{t})=\alpha_{3}+\int_{0}^{\mathrm{t}} \frac{\mathrm{~h}}{\mathrm{I}_{3}} \mathrm{~g}_{3}(\tau) \mathrm{d} \tau \tag{5}
\end{equation*}
$$

This shows that $x_{3}$ can be controlled independently of $x_{1}$ and $x_{2}$, but $x_{3}$ can influence in (3) variables $x_{1}$ and $x_{2}$. We suppose that the rapid reaction response time is short and $x_{3}$ may be considered constant $x_{3}=\alpha_{3}$, so $g_{3} \cong 0$. We also suppose that forces $g_{1}, g_{2}$ are bounded

$$
\begin{equation*}
\left|\mathrm{g}_{1}(\mathrm{t})\right| \leq \mathrm{L},\left|\mathrm{~g}_{2}(\mathrm{t})\right| \leq \mathrm{L} \tag{6}
\end{equation*}
$$

In this case the system (3) is linearized and we introduce the control function $\mathrm{u}\left(\mathrm{u}_{1}(\mathrm{t}), \mathrm{u}_{2}(\mathrm{t})\right)$ to control optimum stabilization of disturbed solution to $\mathrm{O}\left(\mathrm{x}_{1}=0, \mathrm{x}_{2}=0\right)$ for system (7) in minimal time.

$$
\left\{\begin{array}{l}
\dot{\mathrm{x}}_{1}=\omega \mathrm{x}_{2}+\mathrm{ku}_{1}(\mathrm{t}) \equiv \mathrm{f}_{1}  \tag{7}\\
\dot{\mathrm{x}}_{2}=-\omega \mathrm{x}_{1}+\mathrm{ku}_{2}(\mathrm{t}) \equiv \mathrm{f}_{2}
\end{array}\right.
$$

where:

$$
\begin{cases}\omega=\frac{\mathrm{I}-\mathrm{I}_{3}}{\mathrm{I}} \alpha_{3} ; & \omega>0  \tag{7’}\\ \mathrm{k}=\frac{\mathrm{l}}{\mathrm{~L}} \mathrm{~L} ; & \mathrm{k}>0 \\ \mathrm{u}_{\mathrm{i}}(\mathrm{t})=\frac{\mathrm{g}_{\mathrm{i}}(\mathrm{t})}{\mathrm{L}} ; & \mathrm{i}=1,2\end{cases}
$$

We note that state equations (7) in the phase space $\left(\mathrm{x}_{1} \mathrm{Ox}_{2}\right), \mathrm{X}\left(\mathrm{x}_{1}(\mathrm{t}) ; \mathrm{x}_{2}(\mathrm{t})\right)$, with control parameters $\left(\mathrm{u}_{1}(\mathrm{t})\right.$; $\left.\mathrm{u}_{2}(\mathrm{t})\right)$ satisfy the conditions:

$$
\left\{\begin{array}{l}
-1 \leq \mathrm{u}_{1}(\mathrm{t}) \leq 1  \tag{8}\\
-1 \leq \mathrm{u}_{2}(\mathrm{t}) \leq 1
\end{array} ; \quad \mathrm{U}:=[-1,1]\right.
$$

and hence the allowable plan $\mathrm{U}\left(\mathrm{u}_{1} \mathrm{Ou}_{2}\right)$ is a compact square.
The technical sense in equations (7) for $U_{i}(t)$ is to find forces $g_{i}(t) \leftrightarrow u_{i}(t)$ to reduce speeds $\left(\mathrm{x}_{1}, \mathrm{x}_{2}\right) \rightarrow(0,0)$ on optimal paths starting from $\mathrm{M}_{0}\left(\alpha_{1}, \alpha_{2}\right)$ at time $\mathrm{t}_{0}$ to reach the final target $\mathrm{O}(0,0)$ at the time $\mathrm{t}_{\mathrm{f}}>\mathrm{t}_{0}$ so the transfer time to be minimal (o.c.p.) [2], [3], [9], [7].

## 3. MINIMAL TIME CRITERION. EXTREMUM PRINCIPLE

Let's consider a system described by the state equations

$$
\begin{equation*}
\dot{\mathrm{x}}_{\mathrm{i}}=\mathrm{f}_{\mathrm{i}}(\mathrm{t}, \mathrm{x}(\mathrm{t}), \mathrm{u}(\mathrm{t})), \mathrm{t} \in\left[\mathrm{t}_{0}, \mathrm{t}_{1}\right] \subseteq \mathrm{R}_{+}, \mathrm{i}=\overline{1, \mathrm{n}} \tag{9}
\end{equation*}
$$

where the state function is $\mathrm{x}(\mathrm{t})=\left(\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathrm{n}}\right), \mathrm{x}_{\mathrm{i}} \in \mathrm{X} \subset \mathrm{R}^{\mathrm{n}}$ and the control function $\mathrm{u}(\mathrm{t})=\left(\mathrm{u}_{1}, \mathrm{u}_{2}, \ldots, \mathrm{u}_{\mathrm{m}}\right) \subset \mathrm{U} \subset \mathrm{R}^{\mathrm{m}}$ with $\mathrm{m} \leq \mathrm{n}$.
Functions $f_{i}$ meet the regularity conditions and $U$ is the allowable domain of parameters $\mathrm{u}_{\mathrm{i}}(\mathrm{t})$. System (9) respects the given initial conditions (I):
(I) $x_{i}\left(t_{0}\right)=x_{i}^{0} \in R, i=\overline{1, n}$
determining the disturbed initial state $X^{0} \in S^{0}$, where $S^{0}$ is the variety on which $X^{0}$ is fixed.

Assuming that Cauchy problem (9) (10) has $x_{i}=x_{i}\left(t, t_{0}, x^{0}, u\right), t \geq t_{0}$ as unique solution, we request that this trajectory transfer the system in the state $X^{1} \in S^{1}$, where $X^{1}$ is fixed on $S^{1}$ (target (final) state - usually steady state in the final moment $t_{1}=t_{f}$ horizon pool) - $\mathrm{t}_{0} \leq \mathrm{t}_{1}$ :
(F) $\mathrm{x}_{\mathrm{i}}\left(\mathrm{t}_{1}\right)=\mathrm{x}_{\mathrm{i}}^{1} \in \mathrm{R}, \mathrm{i}=\overline{1, \mathrm{n}}$

The final moment $t_{1}$ will be determined using "minimal time criterion" - rapid response $\min _{u \in \mathrm{U}}\left(\mathrm{t}_{1}-\mathrm{t}_{0}\right)=\mathrm{t}^{*}$, extremizing the performance index $\mathrm{J}=\mathrm{J}[\mathrm{u}][1]$, [2], [9].
Let's consider the index functional, see [1], [9], [10]:

$$
\begin{equation*}
\mathrm{J}(\mathrm{u})=\int_{\mathrm{t}_{0}}^{\mathrm{t}_{1}} \mathrm{f}_{0}(\mathrm{x}, \mathrm{u}, \mathrm{t}) \mathrm{dt} \tag{12}
\end{equation*}
$$

where $f_{0}$ is a characteristic function (Lagrangean) with:

$$
\begin{equation*}
\dot{\mathrm{x}}_{0}(\mathrm{t}) \equiv \mathrm{f}_{0}(\mathrm{t}, \mathrm{x}, \mathrm{u}) ; \mathrm{x}_{0}\left(\mathrm{t}_{0}\right)=\mathrm{C}_{0} \tag{13}
\end{equation*}
$$

The optimal control problem (P.C.O.) is to determine an optimal admissible command $\mathrm{u}^{*} \in \mathrm{U}$ to extremize (12) so that the original system (9) (10) (I) is transferred to the final system (11) ( F ) in minimal time (minimum criteria).
"Extreme Pontriaguine principle" (P.E.) will be calling to solve it. We auxiliary introduce the multipliers $\lambda(\mathrm{t})=\left(\lambda_{0}(\mathrm{t}), \lambda_{1}(\mathrm{t}), \ldots, \lambda_{\mathrm{n}}(\mathrm{t})\right)$ as non-null solution of the adjunct system [1] [9] [7] [10]:

$$
\begin{equation*}
\dot{\lambda}_{\mathrm{i}}=-\sum_{\mathrm{j}=0}^{\mathrm{n}}\left(\frac{\partial \mathrm{f}_{\mathrm{j}}}{\partial \mathrm{x}_{\mathrm{i}}}\right)_{0} \lambda_{\mathrm{i}} ; \lambda_{\mathrm{i}}\left(\mathrm{t}_{0}\right)=\mathrm{c}_{\mathrm{i}}, \mathrm{i}=\overline{1, \mathrm{n}} \tag{14}
\end{equation*}
$$

associated with (9)...(13) with arbitrary constants $c_{i}$ (but not all of them arbitrary), which will finally become the controller parameters.
We note that (14), if it's linearized: $\dot{\mathrm{X}}=\mathrm{AX}+\mathrm{BU}$ in the final null position (O) vicinity, $\mathrm{A}=\left(\mathrm{a}_{\mathrm{ij}}\right)=\left(\frac{\partial \mathrm{f}_{\mathrm{i}}}{\partial \mathrm{x}_{\mathrm{j}}}\right)_{0}$ i.e. $\dot{\lambda}=-\mathrm{A}^{\prime} \lambda$, where $\dot{\lambda}=-\mathrm{A}^{\prime} \lambda$, $\mathrm{A}^{\prime}$ is the transposed matrix.

We consider the lagrangean like $f_{0}$ and (12) :

$$
\begin{align*}
& \mathrm{L}(\mathrm{t}, \mathrm{x}(\mathrm{t}), \mathrm{u}(\mathrm{t})) \equiv \mathrm{f}_{0}(\mathrm{x}, \mathrm{u}, \mathrm{t}) \equiv 1, \dot{x}_{0}=\mathrm{f}_{0} \equiv 1  \tag{15}\\
& \mathrm{~J}(\mathrm{u})=\int_{\mathrm{t}_{0}}^{\mathrm{t}_{1}} \mathrm{Ldt}=\mathrm{t}_{1}-\mathrm{t}_{0} ; \min _{\mathrm{u}} \mathrm{~J}(\mathrm{u})=\mathrm{J}\left(\mathrm{u}^{*}\right)=\min _{\mathrm{u}}\left(\mathrm{t}_{1}-\mathrm{t}_{0}\right)=\mathrm{t}^{*} \tag{16}
\end{align*}
$$

We build the generalized Hamiltonian [9] [10] associated with (11) (12) (13) (14):

$$
\begin{equation*}
\mathrm{H}(\mathrm{t}, \mathrm{x}(\mathrm{t}), \lambda(\mathrm{t}), \mathrm{u}(\mathrm{t}))=\lambda_{0} \dot{\mathrm{x}}_{0}+\sum_{\mathrm{i}=1}^{\mathrm{n}} \lambda_{\mathrm{i}} \dot{\mathrm{x}}_{\mathrm{i}} \tag{17}
\end{equation*}
$$

where $\dot{\mathrm{x}}_{0}=\mathrm{f}_{0} \equiv 1$, with $\dot{\lambda}_{0}=\left(\frac{\partial \mathrm{f}_{0}}{\partial \mathrm{x}}\right)_{0} \lambda \equiv 0, \lambda_{0} \equiv \mathrm{C}_{0}$
From (11) and (17) we have:

$$
\begin{equation*}
\mathrm{H} \equiv \lambda_{0}+\sum_{\mathrm{i}=1}^{\mathrm{n}} \lambda_{\mathrm{i}} \mathrm{f}_{\mathrm{i}}(\mathrm{t}, \mathrm{x}, \mathrm{u}) \tag{18}
\end{equation*}
$$

and we built the canonic attached and adjunct system [1] [2] [7] [9]:

$$
\begin{align*}
& \dot{\mathrm{x}}_{\mathrm{i}}=\frac{\partial \mathrm{H}}{\partial \lambda_{\mathrm{i}}}  \tag{19}\\
& \dot{\lambda}_{\mathrm{i}}=-\frac{\partial \mathrm{H}}{\partial \mathrm{x}_{\mathrm{i}}}, \mathrm{i}=\overline{1, \mathrm{n}}, \mathrm{t} \in\left[\mathrm{t}_{0}, \mathrm{t}_{1}\right] \tag{20}
\end{align*}
$$

with $\mathrm{u}_{\mathrm{i}} \in[-1,1]$ and initial conditions $\mathrm{x}_{\mathrm{i}}\left(\mathrm{t}_{0}\right)=\mathrm{x}_{\mathrm{i}}^{0}, \lambda_{\mathrm{i}}\left(\mathrm{t}_{0}\right)=\mathrm{c}_{\mathrm{i}}$. This system is:

$$
\begin{equation*}
\dot{\mathrm{x}}_{\mathrm{i}}=\mathrm{f}_{\mathrm{i}}(\mathrm{t}, \mathrm{x}, \mathrm{u}) ; \dot{\lambda}_{\mathrm{i}}=-\lambda_{\mathrm{i}} \sum_{\mathrm{j}=1}^{\mathrm{n}}\left(\frac{\partial \mathrm{f}_{\mathrm{j}}}{\partial \mathrm{x}_{\mathrm{i}}}\right)_{0} \tag{21}
\end{equation*}
$$

with $2 n$ unknowns: $x_{i}, \lambda_{i}$ and $2 n$ conditions, where $u^{*}$ is previously and optimal chosen. "Pontreaguine minimum principle" theorem ([1] [2] [9]): A necessary condition for the existence of an optimal solution $\mathrm{u}^{*} \in \mathrm{U} \quad\left(\mathrm{x}_{\mathrm{i}} \in[-1,1]\right)$ minimizing (11), $\min _{\mathrm{u}} \mathrm{J}(\mathrm{u})=\mathrm{J}\left(\mathrm{u}^{*}\right) \equiv \min _{\mathrm{u}}\left(\mathrm{t}_{1}-\mathrm{t}_{0}\right)=\mathrm{t}^{*} \quad$ associated with (9), (10), (11), (18), where $\min _{\mathrm{u}} \mathrm{H}(\mathrm{t}, \mathrm{x}, \lambda, \mathrm{u})=\mathrm{H}^{*}\left(\mathrm{t}, \mathrm{x}, \lambda, \mathrm{u}^{*}\right)=0, \forall(\mathrm{t}, \mathrm{x}, \lambda)$ is that trajectories $\mathrm{x}_{\mathrm{i}}, \lambda_{\mathrm{i}}$ respect (19), (20), (21) $\forall t \in\left[t_{0}, t^{*}\right]$ with:

$$
\begin{equation*}
\mathrm{H}(\mathrm{t}, \mathrm{x}, \lambda, \mathrm{u}) \geq \mathrm{H}^{*}\left(\mathrm{t}, \mathrm{x}, \lambda, \mathrm{u}^{*}\right) \geq 0 ; \min (\mathrm{H})=\mathrm{H}^{*}\left(\mathrm{t}^{*}, \mathrm{x}^{*}, \lambda^{*}, \mathrm{u}^{*}, \mathrm{C}\right)=0 \tag{22}
\end{equation*}
$$

## Remarks:

1) We may take $\lambda_{0}=\mathrm{c}_{0} \equiv 1$ and $\mathrm{H}(\mathrm{t})$ is minimized determining the vector $\lambda=\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{\mathrm{n}}\right)$ so that the speed $\dot{\mathrm{X}}=\left(\dot{\mathrm{x}}_{\mathrm{i}}\right)$ projection on $\lambda$ vector to be minimum: $\min \left(\sum_{\mathrm{i}=1}^{\mathrm{n}} \lambda_{\mathrm{i}} \dot{\mathrm{x}}_{\mathrm{i}}\right)$.
2) After building $H$, (17) and (18) with $H=H(u)$, we find $u^{*}$ with $-1 \leq u_{i} \leq 1$, generally with $\frac{\partial H}{\partial u}=0$; but, if $H$ is linear in $u, H=a+b u_{1}+\mathrm{cu}_{2}$, then, according to linear programming with $H \geq 0$ in compact square $u(t) \in U$ included in ( $H, u 1, u 2$ ) space, the minimum $H\left(u^{*}\right)=0$ will be in the square tips $u^{*}=\left\{\left(u_{1}^{*}=-1, u_{2}^{*}=1\right),\left(\mathrm{u}_{1}^{*}=1, \mathrm{u}_{2}^{*}=-1\right)\right\}$; the solutions will be $\mathrm{x}=\mathrm{x}\left(\mathrm{t}, \mathrm{u}^{*}\right), \lambda=\lambda\left(\mathrm{t}, \mathrm{u}^{*}\right)$.

## 4. ANGULAR SPEEDS STABILIZATION OPTIMAL CONTROL

We still apply the algorithm (9) - (22) to (1) - (8); and build Hamiltonian (17) (18) associated with the system (7):

$$
\begin{equation*}
\mathrm{H}=1+\lambda_{1} \dot{\mathrm{x}}_{1}+\lambda_{2} \dot{\mathrm{x}}_{2}=1+\lambda_{1} \omega \mathrm{x}_{2}-\lambda_{2} \omega \mathrm{x}_{1}+\lambda_{1} \mathrm{ku}_{1}+\lambda_{2} \mathrm{ku}_{2} \geq 0 \tag{23}
\end{equation*}
$$

We note that $\mathrm{H}=\mathrm{H}\left(\mathrm{u}_{1}, \mathrm{u}_{2}\right)=\mathrm{a}+\mathrm{bu}_{1}+\mathrm{cu}_{2}$ is linear and positive in the compact square $\mathrm{u}_{1}(\mathrm{t}) \in[-1 ; 1], \mathrm{u}_{2}(\mathrm{t}) \in[-1 ; 1]$; so in the space $\left(\mathrm{H}, \mathrm{u}_{1}, \mathrm{u}_{2}\right) \mathrm{H}$ has a null minimum in the square tips: $H \geq \underset{k \in U}{H_{\text {min }}}=H\left(u_{1}^{*}, u_{2}^{*}\right)=0$

$$
\begin{equation*}
\text { So, if } u_{1}^{*}=-\operatorname{sgn}\left(\lambda_{1}\right) ; u_{2}^{*}=-\operatorname{sgn}\left(\lambda_{2}\right) \tag{24}
\end{equation*}
$$

the trajectories $\mathrm{C}_{1}^{ \pm}\left(\mathrm{u}_{1}=1, \mathrm{u}_{2}=-1\right)$ or $\mathrm{C}_{1}^{\mp}\left(\mathrm{u}_{1}=-1, \mathrm{u}_{2}=1\right)$ will be obtained, and they will tend to origin $\mathrm{O}\left(\mathrm{x}_{1}=0, \mathrm{x}_{2}=0\right)$.

The system is autonomic and $\mathrm{u}^{*}$ is pulse-type. It results that the controller will be a relay-type one, acting with or without commutation [1] [2] [7]. We solve the canonic system (13)(14), effectively (7) with initial conditions $x_{i}\left(\mathrm{t}_{0}=0\right)=\alpha_{i}, i=1,2$ and $u \in U$ :

$$
\begin{gather*}
\left\{\begin{array}{l}
\omega \mathrm{x}_{1}-\mathrm{u}_{2}^{*} \mathrm{k}=\left(\omega \alpha_{1}-\mathrm{u}_{2}^{*} \mathrm{k}\right) \cos \omega \mathrm{t}+\left(\omega \alpha_{2}+\mathrm{u}_{1}^{*} \mathrm{k}\right) \sin \omega \mathrm{t} \\
\omega \mathrm{x}_{2}+\mathrm{u}_{1}^{*} \mathrm{k}=-\left(\omega \alpha_{1}-\mathrm{u}_{2}^{*} \mathrm{k}\right) \sin \omega \mathrm{t}+\left(\omega \alpha_{2}+\mathrm{u}_{1}^{*} \mathrm{k}\right) \cos \omega \mathrm{t}
\end{array}\right.  \tag{25}\\
\left(\mathrm{x}_{1}-\frac{\mathrm{u}_{2}^{*} \mathrm{k}}{\omega}\right)^{2}+\left(\mathrm{x}_{2}+\frac{\mathrm{u}_{1}^{*} \mathrm{k}}{\omega}\right)^{2}=\left(\alpha_{1}-\frac{\mathrm{u}_{2}^{*} \mathrm{k}}{\omega}\right)^{2}+\left(\alpha_{2}+\frac{\mathrm{u}_{1}^{*} \mathrm{k}}{\omega}\right)^{2} \tag{26}
\end{gather*}
$$

We note that these trajectories are circles with centers $\mathrm{O}^{*}\left(\frac{\mathrm{u}_{2}^{*} \mathrm{k}}{\omega},-\frac{\mathrm{u}_{1}^{*} \mathrm{k}}{\omega}\right)$ and radius $R^{2}=\left(\alpha_{1}-\frac{u_{2}^{*} k}{\omega}\right)^{2}+\left(\alpha_{2}+\frac{u_{1}^{*} k}{\omega}\right)^{2}$, but they are not reaching the target point $O(0,0)$ for $\forall\left(\alpha_{1}, \alpha_{2}\right)$. If in (26) $\mathrm{x}_{1} \equiv 0, \mathrm{x}_{2} \equiv 0$, we will get for $(\alpha)=(\mathrm{x})$ the compatible circles -a bi-local problem.

$$
\begin{align*}
& \left(\omega x_{1}-u_{2}^{*} \mathrm{k}\right)^{2}+\left(\omega x_{2}+u_{1}^{*} \mathrm{k}\right)^{2}=2 \mathrm{k}^{2} ; \mathrm{R}=\frac{\mathrm{k} \sqrt{2}}{\omega} ; \mathrm{O}_{0}^{*}\left(\frac{\mathrm{u}_{2}^{*} \mathrm{k}}{\omega},-\frac{\mathrm{u}_{1}^{*} \mathrm{k}}{\omega}\right)  \tag{27}\\
& \left\{\begin{array}{l}
\mathrm{x}_{1}-\frac{\mathrm{u}_{2}^{*} \mathrm{k}}{\omega}=\frac{\mathrm{k} \sqrt{2}}{\omega} \cos \theta \\
\mathrm{x}_{2}+\frac{\mathrm{u}_{1}^{*} \mathrm{k}}{\omega}=\frac{\mathrm{k} \sqrt{2}}{\omega} \sin \theta
\end{array} ; \theta=\theta_{0}+\omega\left(\mathrm{t}-\mathrm{t}_{0}\right)\right. \tag{28}
\end{align*}
$$

We note that the origin is on the circles from this family and their centers are on the first bisecting line $\left(\mathrm{Oz}_{1}\right)$ of the system $\mathrm{x}_{1} \mathrm{Ox}_{2}$ or on the second one $\left(\mathrm{Oz}_{2}\right)$, with the $\left(\mathrm{z}_{1} \mathrm{Oz}_{2}\right)$ axis system, see figure 2a. Choosing the optimal circles depends on the optimal control $u^{*}$ so that $H^{*}\left(u^{*}\right) \geq 0$; if the $X$ system would be rotated with $\frac{\pi}{4}: z \rightarrow z=x \cdot e^{i \frac{\pi}{4}}$, we note that from $\mathrm{H}\left(\mathrm{u}^{*}\right) \geq 0$, with (23) and (24) it results the trajectory on the upper (towards $\mathrm{Oz}_{1}$ ) half-circles $\left\{\mathrm{C}_{1}^{*}\right\}$ from the first quadrant and the lower half-circles, $\left\{\mathrm{C}_{2}^{*}\right\}$ from the third quadrant, i.e.: $\left\{\mathrm{C}_{10}^{\mp}: \mathrm{u}_{1}^{*}=-1, \mathrm{u}_{2}^{*}=1\right\} \cup\left\{\mathrm{C}_{20}^{ \pm}: \mathrm{u}_{1}^{*}=1, \mathrm{u}_{2}^{*}=-1\right\}$, with centers respectively: $\quad \mathrm{O}_{10}^{\mp}\left(\frac{\mathrm{k}}{\omega}, \frac{\mathrm{k}}{\omega}\right)$ and $\mathrm{O}_{20}^{ \pm}\left(-\frac{\mathrm{k}}{\omega},-\frac{\mathrm{k}}{\omega}\right)$. Choosing the initial point $\mathrm{M}^{0}\left(\alpha_{1}^{0}, \alpha_{2}^{0}\right) \in \mathrm{C}_{10}^{\mp}$ in the moment $\mathrm{t}_{0}$, corresponds to the angle $\theta_{0}$ towards $\mathrm{Ox}_{1}$ : $\tan \theta_{0}=\frac{\alpha_{2}^{0}-\frac{\mathrm{k}}{\omega}}{\alpha_{1}^{0}-\frac{\mathrm{k}}{\omega}} ;$
It may be observed on figure 2a that $\theta_{0} \in\left[\frac{\pi}{4}, \frac{5 \pi}{4}\right]$, with $\theta=\omega t+\frac{\pi}{4}$.

$$
\begin{equation*}
\theta_{0} \in\left[\frac{\pi}{4}, \frac{5 \pi}{4}\right], \mathrm{t}_{0} \in\left[0, \frac{\pi}{\omega}\right], \mathrm{t}^{*}=\frac{1}{\omega}\left(\frac{5 \pi}{4}-\theta_{0}\right), \alpha_{1}^{0}>0, \alpha_{2}^{0}>0 \tag{29}
\end{equation*}
$$

Analog and asymmetrically for the circle $\mathrm{C}_{2}^{ \pm}$.
Remark: The optimal trajectories are periodical $\mathrm{T}=\frac{2 \pi}{\omega} ;\left\{\mathrm{C}_{1 \mathrm{j}}^{\mp}\right\} \cup\left\{\mathrm{C}_{2 \mathrm{j}}^{ \pm}\right\}$are tangent half-circles, with centers $\mathrm{O}_{1 \mathrm{j}}^{\mp}\left((2 \mathrm{j}+1) \frac{\mathrm{k}}{\omega},(2 \mathrm{j}+1) \frac{\mathrm{k}}{\omega}\right), \mathrm{O}_{2 \mathrm{j}}^{ \pm}\left(-(2 \mathrm{j}+1) \frac{\mathrm{k}}{\omega},-(2 \mathrm{j}+1) \frac{\mathrm{k}}{\omega}\right), \mathrm{j}=0,1,2, \ldots$ and radius $\mathrm{R}=\frac{\mathrm{k} \sqrt{2}}{\omega}$; for example, if the starting point is $\mathrm{M}_{0 \mathrm{j}} \in \mathrm{C}_{1 \mathrm{j}}^{\mp}$, then the minimal time will be $\mathrm{t}^{*}=\mathrm{j} \frac{\mathrm{k}}{\omega}+\frac{1}{\omega}\left[\frac{5 \pi}{4}-\theta_{0}\left(\mathrm{M}_{0 \mathrm{j}}\right)\right]$, without relay commutation.

There are situations when the starting point is not on the small half-circles, for example $\mathrm{P}_{0}\left(\gamma_{1}, \gamma_{2}\right)$ in the third quadrant in figure 2 b . In this case we choose from $\mathrm{C}_{2 \mathrm{j}}^{ \pm}$a half-circle $\mathrm{O}_{2 \mathrm{j}}^{ \pm}$with radius $\mathrm{R}_{\Gamma}$ denoted $\Gamma^{ \pm}$. This circle crosses one of the half-circles $C_{1 j}^{\mp}$. This is the commutation moment ( $u_{i} \rightarrow-u_{i}, i=1,2$ ), the new trajectory starting from Q and ending in origin.

b)

FIG. 2: Optimal trajectories
a) With no relay commutation b) with relay commutation

We solve the adjunct system (14-20) with H from (23):

$$
\begin{align*}
& \dot{\lambda}_{1}=-\omega \lambda_{2}, \dot{\lambda}_{2}=\omega \lambda_{1}, \lambda_{1}(\mathrm{t}=0)=\mathrm{c}_{1}^{+}, \lambda_{2}(\mathrm{t}=0)=\mathrm{c}_{2}^{-}  \tag{30}\\
& \lambda_{1}=\mathrm{c}_{1} \cos \omega \mathrm{t}+\mathrm{c}_{2} \sin \omega \mathrm{t} ; \lambda_{2}=\mathrm{c}_{1} \sin \omega \mathrm{t}-\mathrm{c}_{2} \cos \omega \mathrm{t}  \tag{31}\\
& \lambda_{1}^{2}+\lambda_{2}^{2}=\mathrm{c}_{1}^{2}+\mathrm{c}_{2}^{2} ; \lambda_{1}=\sqrt{\mathrm{c}_{1}^{2}+\mathrm{c}_{2}^{2}} \cos \left(\omega \mathrm{t}-\varphi_{0}\right) ; \lambda_{2}=\sqrt{\mathrm{c}_{1}^{2}+\mathrm{c}_{2}^{2}} \sin \left(\omega \mathrm{t}-\varphi_{0}\right)  \tag{32}\\
& \tan \varphi_{0}=\frac{\mathrm{c}_{2}}{\mathrm{c}_{1}} ; \varphi_{0}=\operatorname{atan}\left(\frac{\lambda_{2}^{0}}{\lambda_{1}^{0}}\right) \tag{33}
\end{align*}
$$

We note that the adjunct system solution (31) describes a circle (32) and the period is the same as $\mathrm{C}_{10}^{\mp}, \mathrm{C}_{20}^{ \pm}$semicircles one, so $\mathrm{C}_{10}^{\mp}$ semicircle description coincides with the description in the same direction of the semicircle upper $\lambda_{2}>0$ and $C_{20}^{ \pm}$description coincides with lower semicircle $\lambda_{2}<0$ in the plane $\left(\lambda_{1} \mathrm{O} \lambda_{2}\right)$.
Choosing the signs for $\mathrm{u}^{*}$ and $\lambda, \mathrm{c}_{1}, \mathrm{c}_{2}$ was determined by interpreting the semi-circles in $\left(\mathrm{z}_{1} \mathrm{Oz}_{2}\right)$ as follows:

$$
\left\{\begin{array}{l}
\mathrm{C}_{10}^{\mp} ; \mathrm{u}_{1}^{*}=-1 ; \lambda_{1}>0 ; \mathrm{c}_{1}>0 ; \mathrm{u}_{2}^{*}=1 ; \lambda_{2}<0 ; \mathrm{c}_{2}<0 \text { pentru } \mathrm{z}_{2} \geq 0  \tag{34}\\
\mathrm{C}_{20}^{ \pm} ; \mathrm{u}_{1}^{*}=1 ; \lambda_{1}<0 ; \mathrm{c}_{1}<0 ; \mathrm{u}_{2}^{*}=-1 ; \lambda_{2}>0 ; \mathrm{c}_{2}>0 \text { pentru } \mathrm{z}_{2} \leq 0
\end{array}\right\}
$$

### 4.1. Optimal Control of the Un-commutated System [1], [2], [7]

Let's suppose that in the initial moment $\mathrm{t}_{0}$ the system is in $\mathrm{M}_{0}\left(\alpha_{1}, \alpha_{2}\right)$ on $\mathrm{C}_{10}^{\mp}$ or $\mathrm{C}_{20}^{ \pm}$, and must reach the (target point) $\mathrm{O}(0.0)$ in minimum time $\mathrm{t}_{1}^{*} ; \alpha_{1}>0, \alpha_{2}>0$ or

## APPLIED MATHEMATICS, COMPUTER SCIENCE, IT\&C

$\alpha_{1}<0, \alpha_{2}<0, \alpha_{i}$ given in the system $\left(\mathrm{x}_{1} \mathrm{Ox}_{2}\right)$ on $\mathrm{C}_{10}^{\mp}$ or $\mathrm{C}_{20}^{ \pm}$(without relay switching).

$$
\begin{equation*}
\mathrm{C}_{10}^{\mp}:\left(\mathrm{x}_{1}-\frac{\mathrm{k}}{\omega}\right)^{2}+\left(\mathrm{x}_{2}-\frac{\mathrm{k}}{\omega}\right)^{2}=\left(\frac{\mathrm{k} \sqrt{2}}{\omega}\right)^{2} ; \mathrm{u}_{1}^{*}=-1 ; \mathrm{u}_{2}^{*}=1 ; \mathrm{t} \in\left[0 ; \frac{\pi}{\omega}\right] \tag{35}
\end{equation*}
$$

$\mathrm{M}_{0}$ corresponds to the angle:

$$
\theta_{0}=\left\{\begin{array}{cc}
\operatorname{atan} \frac{\alpha_{2}-\frac{\mathrm{k}}{\omega}}{\alpha_{1}-\frac{\mathrm{k}}{\omega}} & \frac{\pi}{4} \leq \mathrm{a} \tan \frac{\alpha_{2}-\frac{\mathrm{k}}{\omega}}{\alpha_{1}-\frac{\mathrm{k}}{\omega}} \leq \frac{\pi}{2}  \tag{36}\\
\pi+\mathrm{a} \tan \frac{\alpha_{2}-\frac{\mathrm{k}}{\omega}}{\alpha_{1}-\frac{\mathrm{k}}{\omega}} & -\frac{\pi}{2} \leq \mathrm{a} \tan \frac{\alpha_{2}-\frac{\mathrm{k}}{\omega}}{\alpha_{1}-\frac{\mathrm{k}}{\omega}} \leq-\frac{\pi}{4}
\end{array} \quad ; \frac{\pi}{4} \leq \theta_{0} \leq \frac{5 \pi}{4}\right.
$$

We find $\mathrm{t}_{0}=\frac{\theta_{0}}{\omega}$ and as in $\mathrm{O}(0.0) \mathrm{t}_{\mathrm{f}}=\frac{\theta_{\mathrm{f}}}{\omega}=\frac{5 \pi}{4 \omega}$, it results $\mathrm{t}_{\text {min }}^{*}=\frac{1}{\omega}\left(\frac{5 \pi}{4}-\theta_{0}\right)$

$$
\begin{equation*}
\mathrm{H}_{0}^{*}\left(\mathrm{t}_{\mathrm{f}}, \mathrm{X}^{*}, \mathrm{U}^{*}, \lambda^{*}\right)=1+\mathrm{k} \lambda_{2}-\mathrm{k} \lambda_{1}=0 \tag{37}
\end{equation*}
$$

With (23), (31-33): $\quad H_{0}^{*}\left(c_{1}, c_{2}\right)=1+k \sqrt{c_{1}^{2}+c_{2}^{2}}\left(\sin \left(\omega t^{*}-\varphi_{0}\right)-\cos \left(\omega t^{*}-\varphi_{0}\right)\right)=0$, by choosing characteristic values $\mathrm{c}_{1}, \mathrm{c}_{2}$ with (33) on microprocessors. Analog if the system starts with $\mathrm{M}_{0} \in \mathrm{C}_{20}^{ \pm}$.

### 4.2. Optimal Control of the Commutated System

Let's suppose that trajectories (26) are starting at $t_{0}$ from $P_{0}\left(\gamma_{1}, \gamma_{2}\right), P_{0} \in \Gamma_{2}^{ \pm}$, not reaching in O ; they intersect with the switching curves $\mathrm{C}_{1}^{\mp}$ in Q and will optimally arrive in $\mathrm{O}(0.0) . \mathrm{P}_{0}$ is in the third quadrant, $\gamma_{1}<0, \gamma_{2}<0$, with $\theta_{0}\left(\mathrm{P}_{0}\right) \in\left[\frac{5 \pi}{4}, \frac{9 \pi}{4}\right]$. We consider the circle $\Gamma_{20}^{ \pm}$(figure 2b), with center $\mathrm{O}_{20}\left(-\frac{\mathrm{k}}{\omega},-\frac{\mathrm{k}}{\omega}\right)$ and radius $R_{\Gamma}^{2}=\left(\gamma_{1}+\frac{k}{\omega}\right)^{2}+\left(\gamma_{2}+\frac{\mathrm{k}}{\omega}\right)^{2} ; \frac{\mathrm{k} \sqrt{2}}{\omega}<\mathrm{R}_{\Gamma}<\frac{3 \mathrm{k} \sqrt{2}}{\omega}$. It results the equation:
$\Gamma_{20}^{ \pm}:\left(\mathrm{x}_{1}+\frac{\mathrm{k}}{\omega}\right)^{2}+\left(\mathrm{x}_{2}+\frac{\mathrm{k}}{\omega}\right)^{2}=\left(\gamma_{1}+\frac{\mathrm{k}}{\omega}\right)^{2}+\left(\gamma_{2}+\frac{\mathrm{k}}{\omega}\right)^{2}$
The Trajectories (39) $\Gamma_{20}^{ \pm}$will intersect (35) $\mathrm{C}_{10}^{\mp}$ in $\mathrm{Q}\left(\beta_{1}, \beta_{2}\right)$, i.e. the commutation point. We solve the system (39)(35): by subtracting the equations the radical axis (A) is obtained, so we'll solve the system \{(35), (A)\} [1][2][7].

$$
\begin{equation*}
\text { (A) } \mathrm{x}_{1}+\mathrm{x}_{2}=\frac{\omega}{4 \mathrm{k}}\left(\gamma_{1}^{2}+\gamma_{2}^{2}++\frac{2 \mathrm{k}}{\omega}\left(\gamma_{1}+\gamma_{2}\right)\right):=\mathrm{E}>0 ; \mathrm{x}_{1}>0 ; \mathrm{x}_{2}>0 \tag{40}
\end{equation*}
$$

From (35) and (40) it results $x_{1}=\beta_{1} ; x_{2}=\beta_{2} ; Q\left(\beta_{1}, \beta_{2}\right)$

$$
\begin{equation*}
\mathrm{x}_{1}=\frac{1}{2}(\mathrm{E}-\delta)>0 ; \mathrm{x}_{2}=\frac{1}{2}(\mathrm{E}+\delta)>0 \text {, where } \delta=\sqrt{\frac{4 \mathrm{k}}{\omega} \mathrm{E}-\mathrm{E}^{2}} \tag{41}
\end{equation*}
$$

Generally, $\theta=\omega t+\frac{5 \pi}{4}$; we will find $\mathrm{t}_{0}\left(\mathrm{P}_{0}\right)$ and $\theta_{0}\left(\mathrm{P}_{0}\right)$, then $\mathrm{t}_{1}(\mathrm{Q})$ and $\theta_{1}(\mathrm{Q})$ :

$$
\begin{align*}
& \theta_{0}\left(\mathrm{P}_{0}\right)=\left\{\begin{array}{rc}
\pi+\mathrm{a} \tan \frac{\gamma_{2}+\frac{\mathrm{k}}{\omega}}{\gamma_{1}+\frac{\mathrm{k}}{\omega}} & \frac{\pi}{4} \leq \mathrm{a} \tan \frac{\gamma_{2}+\frac{\mathrm{k}}{\omega}}{\gamma_{1}+\frac{\mathrm{k}}{\omega}} \leq \frac{\pi}{2} \\
2 \pi+\operatorname{atan} \frac{\gamma_{2}+\frac{\mathrm{k}}{\omega}}{\gamma_{1}+\frac{\mathrm{k}}{\omega}} & -\frac{\pi}{2} \leq \mathrm{a} \tan \frac{\gamma_{2}+\frac{\mathrm{k}}{\omega}}{\gamma_{1}+\frac{\mathrm{k}}{\omega}} \leq-\frac{\pi}{4}
\end{array} ; \frac{5 \pi}{4} \leq \theta_{0} \leq \frac{9 \pi}{4}\right.  \tag{42}\\
& \theta_{1}(Q)=2 \pi+a \tan \frac{\beta_{2}+\frac{k}{\omega}}{\beta_{1}+\frac{k}{\omega}}  \tag{42'}\\
& \mathrm{t}_{1}^{*}=\mathrm{t}_{1}^{1}-\mathrm{t}_{0}^{1}=\frac{1}{\omega}\left[\theta_{1}(\mathrm{Q})-\theta_{0}\left(\mathrm{P}_{0}\right)\right] \tag{43}
\end{align*}
$$

which is the $\mathrm{P}_{0} \mathrm{Q}$ arc travel time.
With $\mathrm{Q}\left(\beta_{1}, \beta_{2}\right)$ determined, we pass on arc QO (on the circle $\mathrm{C}_{10}^{\mp}$ ) respecting the determinations (35) - (38) and replacing $\left(\alpha_{1}, \alpha_{2}\right)$ with $\left(\beta_{1}, \beta_{2}\right)$ in the second stage.

$$
\begin{align*}
& \theta_{0}^{2}(\mathrm{Q})=\left\{\begin{array}{cc}
\beta_{1}-\frac{\mathrm{k}}{\omega} & \frac{\pi}{4} \leq \mathrm{a} \tan \frac{\beta_{2}-\frac{\mathrm{k}}{\omega}}{\beta_{1}-\frac{\mathrm{k}}{\omega}} \leq \frac{\pi}{2} \\
\mathrm{a} \tan & \beta_{1}-\frac{\mathrm{k}}{\omega} \\
\pi+\mathrm{a} \tan \frac{\beta_{2}-\frac{\mathrm{k}}{\omega}}{\beta_{1}-\frac{\mathrm{k}}{\omega}} & -\frac{\pi}{2} \leq \mathrm{a} \tan \frac{\beta_{1}-\frac{\mathrm{k}}{\omega}}{\beta_{2}} \leq-\frac{\pi}{4}
\end{array} \quad ; \frac{\pi}{4} \leq \theta_{0}^{2} \leq \frac{5 \pi}{4}\right.  \tag{44}\\
& \mathrm{t}_{0}^{2}(\mathrm{Q})=\frac{\theta_{0}^{2}}{\omega} ; \mathrm{t}_{2}^{*}(\mathrm{Q})=\frac{1}{\omega}\left(\frac{5 \pi}{4}-\theta_{0}^{2}\right) \tag{44’}
\end{align*}
$$

The final minimal time for the trajectories (35) and (39) is

$$
\begin{equation*}
\mathrm{t}^{*}=\mathrm{t}_{1}^{*}+\mathrm{t}_{2}^{*} \tag{45}
\end{equation*}
$$

and $\mathrm{H}^{*}(\mathrm{O}) \equiv 0, \mathrm{H}^{*}\left(\mathrm{t}_{2}^{*}, \mathrm{X}^{*}, \mathrm{U}^{*}, \lambda^{*}\right)=\mathrm{H}\left(\mathrm{c}_{1}, \mathrm{c}_{2}\right) \equiv 0$ is used after (38).
Numerical and graphic applications were developed for the two above mentioned situations.

## Remark:

If the speeds system is amortized - resistance terms (elastic damped oscillator) appear - trajectories are spiral arcs. The study of this case is analogous to those presented in the paper.
